Gridcoin - Performing Meaningful Scientific Computations Instead of Inverting Hashes with Proof of Work

Gridcoin Development Team Technical Whitepaper teamgridcoin.slack.com

August 22, 2017

Abstract

This whitepaper describes how Gridcoin makes it possible to reward running scientific simulations with cryptocurrency in a completely decentralized way. Gridcoin is heavily based on Bitcoin [1] with the outstanding exception that Proof of Work where energy is wasted in inverting a hash function is replaced with the novel approach of Proof of Stake [2] linked to Distributed Proof of Research [3], developed on purpose for gridcoin. The voting mechanism embedded in the blockchain which allows to choose which scientific projects to include in Proof of Research is outlined. In conclusion, an outlook is given on how Gridcoin could complement the way science is funded, sparking competition between traditionally funded science and gridcoin funded science.

1 Introduction

An increased quality of living in a society often coincides with an increase in that societys ability to freely gather and process data. Distributed processing, also known as grid computing, offers a tool by which massive quantities of data can be processed at speeds tens of thousands of times faster than any centralized super computer. This speed is directly proportional to the advancement of

2

processing technology, currently progressing in accordance with Moores law.

At the same time, the Idle Processing Potential (IPP) which already exists in digital societies is severely underutilized. From cell phones to personal computers to office workstations, the combined IPP of the world overshadows even the most robust decentralized super-computer, Bitcoin. Gridcoin seeks to create a decentralized and sustainable distributed processing network which prioritizes both the utilization of IPP and the creation of a free to host ecosystem for researchers and individuals with data to process. To accomplish this goal, Gridcoin has created a block-chain based digital asset which rewards individuals and entities which volunteer their IPP to the grid computing network, BOINC. A single GRC represents the value prescribed to a volunteered unit of IPP on the BOINC network. The Gridcoin blockchain is secured through Proof of Stake. Rewards are distributed through a protocol developed by Gridcoin called Distributed Proof of Research, or DPoR.

BOINC, The Berkeley Open Infrastructure for Network Computing, is an open-source distributed processing network which provides scientists and enthusiasts with a means to host data for free. BOINC has been operating since 2002 and has and continues to process data that helps map the Milky Way, detect near earth asteroids, find prime numbers, fold proteins, test cures and vaccines, test chemical and molecular combinations, Search for Extraterrestrial Life (SETI), and more.

By directly rewarding those who volunteer their idle processing power to BOINC, Gridcoin creates an ecosystem in which valuable data, or a worthwhile project, is defined by an open market of science instead of a market of payto-play. In other words, volunteers will move their IPP to projects which they deem of value with no need to consider the reward they will receive.

Although there are other configurations, a typical node runs both the BOINC client to download, execute and report results of scientific computations and the Gridcoin client. The gridcoin client performs several functions: like a bitcoin wallet it allows to transfer money from different addresses, it keeps the blockchain with transactions up to date talking to other nodes and verifying each new block for validity and tries to stake other blocks on the blockchain by collecting new transactions. The coinstake in the proposed new blocks for the own wallet corresponds to the amount of work done on BOINC expressed in gridcoins.

TODO: do nice figure about single node with Gridcoin/BOINC. TODO: do nice figure about network of nodes running Gridcoin/BOINC.

1.1 BOINC

BOINC is a system for distributing the workload of scientific simulations. Users of BOINC have a client running that solves work units (WU) for the specific projects. A work unit consists of code and specific parameters for which the code is run. After the work unit is completed the BOINC client sends back the

results to the BOINC servers, where the results are analyzed.

TODO: update project list One example for a BOINC project is the World Community Grid [11], which consists of various other projects, for example to solve cancer or beat Ebola. SETI@home [20], which looks for signs of alien life by monitoring electromagnetic radiation from space for patterns, is another well-known project. In total there are about 40 BOINC projects, but only the BOINC projects on the [Whitelist] help users earn Gridcoins.

The information which researcher has computed how many work units is stored on the BOINC server. The unit of work done is a credit (cobblestone), which is 1,000 double-precision MFLOPS based on the Whetstone benchmark [Whetstone]. The RAC is the average amount of credits earned per day.

A CPID (Cross Project Identifier) is a number that links together the participation of a single user in all the different projects with a single common identifier, with a CPID one can see the research done by one user over all different projects this user participates in.

There are also teams in BOINC, users can join teams and the work done by each member of the team is added to get the work done by the team. It is necessary for a Gridcoin-researcher to be a part of team ?Gridcoin?, which on some projects is listed as ?gridcoin?, lowercase.

1.2 Gridcoin Client

TODO:

1.3 Setting it up

For setting up BOINC and the Gridcoin client to earn Gridcoins by running scientific simulations on your computer follow the tutorial on gridcoin.us The steps involved are:

- Install BOINC
- Add projects to BOINC
- Install and configure Gridcoin wallet so that it is linked to BOINC
- Acquire gridcoins and move them to your wallet
- Send a beacon so that the wallet CPID is persisted in the blockchain
- Wait until client manages to stake first block with PoS and DPoR reward for your wallet.

2 Neural Network

TODO: explain that the name is misleading.

Gridcoin uses a distributed system to come to a consensus how much work was done by each user. For this each node (Gridcoin client) asks each BOINC project server, what the current RAC of each member of team Gridcoin is. Using the Google Distributed File System [21] the nodes exchange the information regarding which user has done how much work. This information is hashed, so each node does not see the exact information from each other node, but the hash can be compared and it can be found out, if the hash of this node is the same as the majority hash of all nodes.

To become a part of the Neural Network, a researcher?s Gridcoin client has to send a ?beacon? containing the CPID and the wallet?s address. This is a transaction with a very small amount of Gridcoins, that links the CPID and wallet-address of this researcher in its meta-information, so that this information is now forever stored in the blockchain.

3 The blockchain

A blockchain, seminal concept invented by Satoshi in 2009 [1], stores all information about all transactions that have taken place. When one knows all transactions, one also knows the current balance of each address. In Proof of Stake [POS] a node is randomly chosen among all nodes to add the next block to the blockchain. A block contains all transactions that have taken place in the network since the last block. The node adding this block is rewarded with Gridcoins. When the node adds a block, it also chooses the next node randomly among all nodes. However, this is not done completely at random, but weighted by the amount of Gridcoins each node holds.

When the probability is weighted by the current amount of Gridcoins, the reward that one gets on average for adding blocks is directly proportional to the amount of Gridcoins in possession (as this is the probability to be chosen to add the next block and get the reward) and thus can be seen as an interest for the user.

4 Rewarding Researchers

Gridcoin does not only want to reward holders of the coin (as in pure Proof of Stake coins such as Peercoin [2]), but wants to reward researchers. Because of this there is an additional reward depending on the amount of research done. This information is read from a superblock. In some blocks, so called superblocks, the majority opinion from the distributed Neural Network, which user has done how much work is also saved as a hash. These blocks are generated once a day. The current amount of research done by each CPID stored in the last superblock can be viewed on [SUPER]. If a node gets chosen and the hash this node contains about the amount of work done by each user is the same as the majority hash stored in the Neural Network, then this node gets to stake the next block and everything starts again. If the hash is not the same as the majority hash, the node gets punished for trying to cheat the system and does not stake, as in any other consensus based cryptocurrency. The actual reward the node gets then depends on the RAC (Recently Averaged Credit [22]) for each project for this user as stored in the superblock.

To understand RAC, we first look at the cobblestone [22]. The cobblestone is

a unit of measure defined as follows: it is 1/200 day (=7 minutes and 12 seconds, 432 seconds) of CPU time on a reference computer that does 1 Gigaflop (= 1 billion floating point operations per second) based on the Whetstone benchmark. A *cobblestone* in other words correspond to 432 seconds * 1 Gigaflop = 432 billion floating point operations.

Recently Averaged Credit is computed as follows: the daily average of cobblestones in last week plus half of the daily average of cobblestones during two weeks ago plus fourth of the daily average during three weeks ago and so on.

We hereby define:

 γ : this is the average RAC done by a user on a particular BOINC project p since last payment to user u identified by CPID.

 Γ : this is the average RAC done by all users particular in Gridcoin on a particular BOINC project p since last payment to user u.

 τ : this is the time expressed in days since last payment to user u.

 Θ : this is the available gridcoin supply per day assigned to BOINC project p

 ${\cal G}$: this is the constant number of grid coins created per day on the grid coin network.

n: this is the number of BOINC projects in the whitelist. Partecipants in whitelisted projects do receive a reward in gridcoins for their computational effort.

The ratio

$$\gamma/\Gamma$$

is the percentage of work done by user u on BOINC project p in respect to all other gridcoin users working on project p.

The amount of coins σ for project p the user u gets, if he was only running project p, is computed:

$$\sigma = (\gamma/\Gamma) \cdot \tau \cdot \Theta$$

As of now the Θ is the same for each project, so

$$\Theta = G/n$$

 γ and Γ are calculated so that in case there were several superblocks since the last payment the average RAC of all those superblocks is used.

The research reward for user u is then the sum of the rewards for each whitelisted project:

$$research reward = \sum_{p=1}^{n} \sigma(p)$$

The total reward for user u is then the reward for the research done by this node plus the reward that any node gets for staking a block, called inflation reward in the next formula:

total reward = inflation reward + research reward

The *inflationreward* depends on the time that passed since the last stake is chosen in a way that it leads to an interest rate of 1.5% per year.

The rewards that contain only inflation reward and no research reward are often called PoS (Proof of Stake) rewards, whereas the rewards containing inflation reward plus research reward are called Proof of Research rewards.

4.1 Coin Supply and security measures

With a fixed daily research coin supply per project $(\Theta = G/n)$ it would not be ensured that the inflation rate is always the same; it could vary depending on how many new researchers join the project p. Because of this, the amount of average payouts over the last 14 days is used as a lagging indicator of how much was paid out recently - if very little was paid out in the last 14 days more is paid out now and the other way round.

G = MaxDailyEmissions - AvqDailyPaymentsPaidInLast14Days

There are also a few security rules. For example time since last payment in days (τ) can not be greater than 6 months, otherwise there is no payment and the coins paid out per user does have a very high upper limit (20000) per stake. The MaxDailyEmissions is set to 50000 gridcoins, which at the current coin supply means an research driven inflation of around 5%. This rate however will grow smaller, as the coin supply grows but the amount of coins produced per day stays the same. Additionally the inflationreward is chosen, so that the interest inflation is around 1.5% per year.

5 Voting Mechanism

6 Transaction Speed

TODO: Bitcoin [1] transaction speed is 7 TPS. Visa/Mastercard is 30 TPS.

6.1 Segregated Witness

possible implementation in gridcoin? block size for sure, but compressing step? TODO: ask developers

6.2 Proximity of neighbours

describe proposal about having nodes connecting to geographical neighbours and still have some random connections. discuss mathematically some implications...

7 OUTLOOK 7

7 Outlook

7.1 Commercial Projects

Commercial Projects: If it is possible to reward users for running specific code on their computers with cryptocurrency, they could also run commercial simulations on their computers basically for free as they are already rewarded by the newly generated cryptocurrency. This would make it possible to offer computing-intensive services much cheaper than is possible now.

7.2 Mining Pool

Pool mining: Making it possible for users to earn Gridcoins by only pointing their BOINC client at the email address of a pool

7.3 Gridcoin Funded Science

TODO: gridcoin funded research

8 Conclusion

One gridcoin a day takes diseases away (TODO: just joking here) Copyright ©2014-2017 the Gridcoin Development Team, all rights reserved.
